Config Max Tool

VMware Configuration Maximums

This Configuration Maximums tool provides the recommended configuration limits for VMware products. When you configure, deploy and operate your virtual and physical equipment, it is highly recommended you stay at or below the maximums supported by your product. The limits presented in the tool are tested, recommended limits, and are fully supported by VMware.

Disclaimer: The limits can be affected by other factors, such as hardware dependencies. For more information about the supported hardware, see the appropriate hardware compatibility guide. It might not be possible to maximize all configuration settings and expect your desired outcome. To ensure that you do not exceed supported configurations for your environment, consult individual solution limits. The recommended configuration maximums do not represent the theoretical possibilities of your product.

INTEGRATION WITH TRUSTED PLATFORM MODULES

A Trusted Platform Module (TPM) is a computer chip/microcontroller that can securely store artifacts used to authenticate the platform (your PC or laptop). These artifacts can include measurements, passwords, certificates, or encryption keys. A TPM can also be used to digitally sign content and store platform measurements that help ensure that the platform remains trustworthy. The [Trusted Computing Group](#) has a detailed overview of what a TPM is and does.

Since ESXi 5.x, ESXi has had support for TPM 1.2. Prior to 6.7 the APIs and functionality of TPM 1.2 was limited to 3rd party applications created by VMware partners.
